

Trigonometric Solution

As a Geometrician, I didn't approve of trigonometric solutions for Geometric problems. But it's academically interesting to develop/study trigonometric solutions confirming Geometric results. For this problem also, I developed a Trigonometric Solution which I am happy to share here.

Question:

ABCD is a quadrilateral with $BC = CD$ and $AB > AD$. The diagonal AC is also the internal bisector of $\angle BAD$. CE is drawn perpendicular to AB . M is the midpoint of BD . EM is joined and produced to meet CD at F .

Prove that $BM = \frac{CE \times FM}{FC}$

Solution : 2

In ΔABC ,

$$\frac{BC}{\sin x} = \frac{AC}{\sin \angle ABC} \dots\dots\dots(1)$$

$$\text{In } \Delta ADC, \frac{CD}{\sin x} = \frac{AC}{\sin \angle ADC} \dots\dots\dots(2)$$

$$BC = CD \text{ (given)} \dots\dots\dots(3)$$

$$(1), (2) \ \& \ (3) \ \rightarrow \sin \angle ABC = \sin \angle ADC$$

$$\therefore \angle ABC = \angle ADC \text{ (or)} = 180 - \angle ADC$$

If $\angle ABC = \angle ADC$, then $\triangle ABC \cong \triangle ADC$ & $AB = AD$

But it is given that $AB > AD$

$\therefore \angle ABC = \angle ADC$ is inapplicable.

$$\therefore \angle ABC = 180 - \angle ADC$$

$\therefore ABCD$ is concyclic.

Now join CM .

$$\text{Let } \angle BAC = \angle DAC = x$$

$$\text{Let } \angle ABD = y$$

$$\therefore \angle ACD = y$$

$$\therefore \angle CBD = \angle CDB = x$$

$$\angle CBE = (x + y) \dots\dots\dots(4)$$

$$\angle CMB = \angle CMD = 90^\circ \dots\dots\dots(5)$$

$$\angle CEB = 90^\circ \text{ (given)} \dots\dots\dots(6)$$

$\therefore EBCM$ is concyclic.

$$\angle EBM = \angle ECM = y$$

$$\angle EBC = \angle FMC = (x + y) \dots\dots\dots(7)$$

$$\angle AOD = (x + y) = \angle MOC \dots\dots\dots(8)$$

(7)& (8) $\rightarrow \triangle CBE \sim \triangle COM$

$$\therefore \angle MCO = \angle ECB = z \text{ (say)} \dots\dots\dots(9)$$

$$\angle MCF = (z + y) \dots\dots\dots(10)$$

\therefore In $\triangle MCF$,

$$\frac{MF}{FC} = \frac{\sin(z+y)}{\sin(x+y)} \dots\dots\dots(11)$$

$$\text{In } \triangle BCM, \sin(z + y) = \frac{BM}{BC} \dots\dots\dots(12)$$

$$\text{In } \triangle BCE, \sin(x + y) = \frac{CE}{BC} \dots\dots\dots(13)$$

$$(11), (12) \text{ \& } (13) \rightarrow \frac{MF}{FC} = \frac{BM}{CE}$$

$$\Rightarrow BM = CE \times \frac{MF}{FC} \text{ proved.}$$
